

CPSA-E is a signal that enables reading control signals coming from the CPSA board. On CPS2, this is bound to GND so all control signals are available.

DEBUG-RANGE enables the output of two unused additional ranges of the address decoder. On CPS2, if the A-board is plugged, this is plugged to GND

This bus multiplexer is a way to see various inputs after buffers. On CPS2, the output is not enabled so pins are just NC, also S0-S2 are bound to GND

SEC-E2 is duplicated on two 3-state outputs. If SEC-E2 is active and ENABLE-3STATE is active then outputs are LOW and BANK-RESET is inactive. Else outputs are Hi-Z, and CPS2 have pull-up resistors on those pins and BANK-RESET is active, disabling OBJRAM bank behaviour.

Note: All the DEBUG output pins are just NC so they can be completely ignored

All pins here are 3 states, they will be Hi-Z if ENABLE is LOW.

All pins here are 3 states, they will be Hi-Z if ENABLE is LOW.

RESET Drives all "ENABLE" pins which will all be active if RESET is inactive. On CPS2, this is bound to a signal coming from MIF which is driven by the voltage detector of VCC. i.e. if CPS2 has a voltage > 4.2V then this chip will work as intended.

DEBUG is a signal that enables a mode where all outputs are enabled including the debug mux. On CPS2, this is directly bound to GND
